Meta Ads Manager App: End-to-End Publishing Blueprint

A comprehensive operational blueprint detailing the standard Meta for Developers application lifecycle—from initial Sandbox configuration to Production Mode approval for custom Ads Management platforms.

Phase	Core Focus Area	Key Output Requirement
Phase 1	Dashboard Configuration	Legal Policies, App Icon, & Asset Mapping
Phase 2	Business Verification	Meta Business Manager Organization Legal Approval
Phase 3	Technical Pre-requisites	Sandbox Activity Logs (Graph API Activity in 30 Days)
Phase 4	Use Case / App Review	Continuous Screencast Video & 2FA Bypass Credentials
Phase 5	Production Mode Switch	Global Toggle Activation to Live Status

Phase 1: Basic Dashboard Configuration

- **Privacy Policy & Terms URL:** You must provide active, public-facing URLs hosted on your production domain. Placeholder text or broken links trigger instant, automated rejection.
- **App Icon Asset:** Upload a high-resolution 1024x1024 pixel graphic representing your branding. It cannot incorporate trademarks or logos owned by Meta (e.g., modified Facebook or Instagram logos).
- **Data Deletion Callback:** Specify a functional URL or a standard text instruction link detailing exactly how users can request the deletion of data synced from their Facebook Ad Accounts.

Phase 2: Meta Business Portfolio Verification

Apps accessing advanced capabilities—including advertising execution and analytical tracking—require organizational legal entity confirmation.

- **Corporate Linking:** Link the application asset directly inside your *Meta Business Manager / Business Portfolio* settings panel.
- **Official Documentation:** Upload officially issued documents matching the exact trading name and address provided (e.g., Articles of Organization, GST/Tax Certificates, or Business Licenses).
- **Domain Mapping:** Perform domain verification inside Business Manager via DNS TXT Record configuration to validate ownership of your platform's base URL domain.

Phase 3: Technical & Sandbox Prerequisites

Before hitting the final submission pipeline, the application dashboard must actively establish valid interaction telemetry to satisfy systemic audits.

- **The 30-Day Activity Mandate:** You must generate at least one valid Graph API request for each target permission (e.g., `ads_management`, `ads_read`) within the 30 days preceding the submission. Meta's validation layer parses runtime logs; zero-activity endpoints cannot be submitted for live access.

- **Test Environment Configuration:** Create a designated 'Test App' child entity or leverage 'Roles' to establish mock profiles. These profiles link mock Ad Accounts loaded with non-billing test campaigns to ensure structural integrity without incurring financial charges.

Phase 4: App Review & Use Case Assets

This is the core human-reviewed step. You must package explicit context regarding implementation.

- **Context Justification Text:** Provide exact, high-clarity descriptions for every capability requested. Explain clearly *what* the app does, *why* the API scope is required for that action, and *how* the target user controls it.
- **Continuous Screencast Requirements:** Deliver a single, raw, unedited, high-definition screen recording. The video capture must comprehensively show the initial user context click, the standard Meta OAuth authorization dialog exposing checkboxes, data intake to the SaaS interface, and the live creation or metric rendering of a test campaign.
- **Reviewer Access Protocols:** Supply fully active test login credentials to a sandbox staging dashboard. You must completely bypass, whitelist, or temporarily deactivate all multi-factor validation layers (2FA, OTP, SMS codes) for this identity so that the globally distributed Meta review team can navigate the ecosystem immediately.

Phase 5: Switching to Production Mode

Following formal approval notification from the App Review board, full live operations can be instantly deployed globally.

- **App Mode Toggle:** Flip the master environment switch located in the primary navigation header of the Meta Developer Platform from **Development** to **Live**.
- **Production API Tokens:** Update your server-side environment variables to handle production-tier user Access Tokens, taking note of expiration intervals requiring systematic renewal logic via long-lived tokens.
